April 1986
Corrosion Mitigation and Management System

AD-A166 807

by

A. Kumar

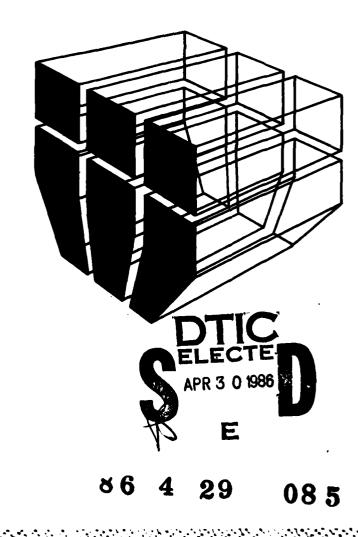

W. Riggs

M. Blyth

The U.S. Army Construction Engineering Research Laboratory (USA-CERL) has developed a pipe corrosion management system, called PIPER, as part of the Corrosion Mitigation and Management System (CM²S). PIPER is a predictive technique based on state-of-the-art mathematical models. USA-CERL developed the program in conjunction with work on some new nondestructive corrosion assessment methods for buried pipes. The program can predict how many leaks a pipe will have in a given year and then "suggest" the most cost-effective solution for correcting the problem. In this way, PIPER ensures the best distribution of dollars spent on replacement and repair of corroded underground pipes. PIPER includes both manual and computerized methods. The computerized part of the system is user-oriented for easy field use.

PIPER has been fielded at two military installations. Results are promising and will be considered in future developmental work with PIPER.

Approved for public release; distribution unlimited.

FOREWORD

This study was conducted for the Assistant Chief of Engineers, Office of the Chief of Engineers (OCE), under Project 4A162731AT41, "Military Facilities Engineering Technology": Task C, "Operation and Maintenance Strategy"; Work Unit 141, "Corrosion Mitigation and Management System." Partial funding was provided by Headquarters, Naval Facilities Engineering Command through work order N0002583WR1107W dated 3 August 1983. The OCE Technical Monitors were L. Keller and B. Wasserman, DAEN-ZCF-U.

The work was performed by the Engineering and Materials Division (EM), U.S. Army Construction Engineering Research Laboratory (USA-CERL). Dr. Robert Quattrone is Chief, EM.

COL Paul J. Theuer is Commander and Director of USA-CERL, and Dr. L. R. Shaffer is Technical Director.

DEMONSTRATION OF THE PIPE CORROSION MANAGEMENT SYSTEM (PIPER)

1 INTRODUCTION

Background

The U.S. Army Construction Engineering Research Laboratory (USA-CERL) has completed preliminary work on concepts for a computerized Pipe Corrosion Management System (PIPER), designed for use by Army installations. 1 As Figure 1 shows, PIPER is a maintenance decision-making tool for assigning priorities to corrosion-related maintenance and repair of underground pipes. It provides fast data storage and retrieval, inventories an installation's pipe network, computes the corrosion status index (CSI), predicts present and future corrosion status based on soil properties, predicts leaks, and gives an economic analysis of maintenance options for budget planning. All output can be formatted into user-defined reports. PIPER is part of the Army's Corrosion Mitigation and Management System (CM²S).

The PIPER data base is custom-designed on a commercially available Boeing Computer Services computer data base manager called "System 2000" (registered trademark of the Intel Corporation).* Data are stored in a tree structure that enables the user to retrieve information based on its connection with other data in the data base. The data can be stored and retrieved through interface programs. PIPER software could be modified to operate on the Vertical Installation on Automatic Baseline (VIABLE) system, an Army-wide automatic data processing (ADP) technology. This development would make PIPER available to more users in the field and would allow all future program development to be written directly onto the system.

When soil properties (pH and resistivity) are entered into the system, PIPER predicts the years in which leaks will occur and the number of cumulative leaks over time; the cumulative data are based on an exponential growth curve. (To review PIPER's typical

output, see Figures 11 through 14 in Technical Report [TR] M-337.)

PIPER also can produce an economic analysis when inflation and interest rates are input. Alternative maintenance strategies can be evaluated and "what if" questions can be answered (Figure 15 in TR M-337). Other user-oriented reports, such as annual work plans and budget optimization schedules, can be formatted.

Computerization is not absolutely necessary; a manual system can achieve some of the same systematic management objectives. However, PIPER's computerized version has many advantages as listed above and in TR M-337. Its disadvantages are the costs of initial investment, training, and implementation.

Objectives

The objectives of this study were to (1) continue investigating methods of nondestructive, underground-pipeline corrosion assessment and (2) demonstrate the computerized version of PIPER and obtain data documenting the system's potential for Army-wide use.

Approach

In continuing the investigation on corrosion assessment methods, USA-CERL began developing the alternating current (a.c.) impedance technique, which exploits similarities between an electrical circuit and a buried pipeline. Meanwhile, sites suitable for demonstrating PIPER's current version were determined. The system was fielded at two installations, and data were evaluated.

Mode of Technology Transfer

It is recommended that information gathered in this work be incorporated into Air Force Technical Manual 5-811-4, *Electrical Design-Corrosion Control* and disseminated as an Engineer Technical Note.

2 NONDESTRUCTIVE PIPELINE CORROSION ASSESSMENT: A.C. IMPEDANCE TECHNIQUE

Methods Used in Current PIPER Version

From the variety of corrosion assessment methods being used or developed in the pipeline industry, USA-CERL considered three possibilities: (1) pipe dig-up for visual inspection, (2) electrical assessment techniques, and (3) estimation using mathematical models.

¹ A. Kumar, E. Meronyk, and E. Segan, Development of Concepts for Corrosion Assessment and Evaluation of Underground Pipelines, Technical Report M-337/ADA140633 (U.S. Army Construction Engineering Research Laboratory, 1983).

^{*}PIPER also can be operated on the Control Data Corporation's (CDC) Cyber network.

Although pipe dig-up with inspection is a highly accurate assessment method, it is also expensive. (Costs range from \$300 to \$1,000 per dig-up, depending on the number of separate inspections.) As alternatives to visual inspection, USA-CERL has been investigating two nondestructive methods that are based on electrical polarization; both the polarization decay technique and the more recent a.c. impedance method are still under development, but show good potential for use with PIPER. Corrosion estimation using mathematical models represents another alternative to inspection. However, the speed and economy of estimation is at the expense of decreased assessment accuracy. For this reason, the PIPER program uses estimation coupled with periodic visual inspection. This dual assessment method maximizes accuracy and minimizes cost.

Future PIPER versions will use electrical assessment instead of inspection, yielding a nondestructive, more economical pipeline management system. The electrical polarization decay technique described in TR M-337 is achieved with direct current (d.c.) (Figure 1 in that report). A newer polarization method being developed uses a.c.

The A.C. Impedance Concept

The terms "resistance" and "impedance" both imply an obstruction to current or electron flow. When the current is d.c., only resistors have this effect. In contrast, with a.c., circuit elements such as capacitors and inductors also can influence electron flow. These elements affect the magnitude of an a.c. waveform along with its time-dependent characteristics or phase.²

Figure 2 represents typical plots of a voltage sine wave (E) applied across a given circuit and the resultant a.c. waveform (I). Note that the two traces differ in amplitude as well as in phase (I leads E). The capacitor in the circuit (in this case, the pipeline corrosion product) is said to "impede" the current flow—thus the term "a.c. impedance." In general, parameters characterizing corrosion behavior can be determined by measuring the frequency dependence of the complex impedance, Z.³ ("Frequency" is defined as the number of alternating cycles through which the voltage goes in 1 sec. By varying the applied frequency, different

responses can be obtained.) When both waveforms are displayed at once on an oscilloscope, a form called a "Lissajous figure" appears (Figure 3). This figure shows that Delta E, Delta I, and Delta I' are readily obtainable. Mathematically:

Z = Delta E/Delta I [Eq 1]

$$\sin \theta = \text{Delta I'/Delta I}$$
 [Eq 2]

$$R = |Z| \cos theta$$
 [Eq 3]

$$-X = |Z| \sin theta$$
 [Eq 4]

R is then plotted on the horizontal axis and -X on the vertical axis. The circuit is tested at several frequencies, and the plot shown in Figure 4 is obtained. This "Cole-Cole" plot allows determination of the purely resistive circuit elements, the polarization resistance, and hence, the capacitance, C. Capacitance is an indicator of the amount of corrosion, with greater amounts of corrosion having larger C values.

Field Testing

The a.c. impedance method must undergo much more development before it will be ready to implement in the field. However, the earlier polarization decay technique is at a higher stage of development and has been field tested. At present, it needs refinement to improve reliability and more experimentation to correct other problems discovered in field testing.

3 DEMONSTRATION OF PIPER

The current computerized version of PIPER (visual inspection coupled with estimation) was fielded at two installations (Fort Riley, KS, and the Naval Supply Depot, Guam) to test whether the system could manage and concisely summarize large data sets. PIPER is a bilevel program designed to provide summary condition reports of whole installations as well as alternative maintenance/replacement evaluations for pipe sections (identified in the condition reports as "failed" or "very poor"; CSI \leq 29). These functions are termed Network Level and Project Level analysis, respectively.

Important components of the Network Level analysis are the: network inventory, frequency report, rank report, projected budget needs, and inspection schedule. In essence, the network inventory is PIPER's data base. Any input parameters stored in the data base

² Basics of AC Impedance Measurements (EG&G Princeton Applied Research, 1984).

³ J. R. Scully and K. J. Bundy, "The Use of Electrochemical Techniques for Measurement of Pipe Steel Corrosion Rates in Soil Environments," presented at the Corrosion Conference '83 (NACE, 1983).

can be recalled in a "specify" report. As the name suggests, whatever parameters requested will appear on the report.

The frequency report is a histogram that summarizes the condition of an installation's pipes. Head-quarters engineers can use this report to compare one installation with another. This report also is a decision-making tool that helps the engineer determine if a single section or many pipe sections should be repaired/replaced. For instance, if an installation's piping is in generally poor condition, it might be better to replace it rather than make repairs.

The prioritization scheme, or rank report, lists pipe sections in ascending order of condition (i.e., worst to best). Since all pipes must have no leaks, the CSI needs to be at least 30 for all pipes in the network. All pipes with CSI below 30 should be replaced. If the replacement budget is limited and the pipes cannot be replaced, stepped replacement, using budget optimization, is the answer.

Many paramters can be stored for each section of pipe (see Figure 10 in TR M-337), Indeed, the PIPER data base can contain more information about piping systems than is normally available at most facilities. Therefore, only a limited number of parameters were documented for the initial implementation at the field sites (information such as leak records and actual year of first leak usually was not available, but could be entered later). USA-CERL personnel visited each facility, obtained biueprints of the piping systems, gathered soil samples from various locations at the facility, consulted with engineering and maintenance staff, and obtained as much information as possible for inputting into the PIPER data base. Contracts were then awarded to integrate this information, partition the blueprints into a logical sequence of pipe identifications and section numbers, and enter the data into the computer data base. (The partitioning and labeling of piping networks was the greatest challenge since standards for labeling sections and proper partitioning procedures have not yet been established.) The contractors also were required to test output via the various reporting methods.

Fort Riley, KS

the state of the s

The entire gas piping system at Fort Riley, KS, was studied. The 78 gas pipes were segmented logically into 535 sections. To calculate the CSI for each section, the following data were gathered: soil resistivity, soil pH, pipe coating material, wall thickness, and year installed; Figure 5 shows this information in the

form of a specify report. Although the year of first leak data (if applicable) would have made the predicted CSI more accurate, this information was unavailable so the CSI was calculated without it. Figures 6 and 7 are the frequency and rank reports generated.

PIPER helped locate trouble spots in the Fort Riley piping network. As a result, new steel pipes combined with cathodic protection systems were installed in FY85. USA-CERL will continue monitoring the Fort Riley piping system. A future version of PIPER will include a cathodic protection monitor, and this feature will be tested at Fort Riley when it is completed.

Naval Supply Depot (NSD) Guam

The structures considered at NSD Guam were:

- 1. Sasa Valley Tank Farm and related piping
- 2. Tenjo Vista Tank Farm and related piping
- 3. Pipelines to the Naval Air Station (NAS).

The structures were built at various times since 1952. The Sasa Valley-to-NAS pipelines were completed in 1977. Tanks in the Sasa Valley system were completed as follows:

- 1. Tanks U-1 through U-16-1952/53
- 2. Tanks U-17 and U-18-1957
- 3. Tanks U-19 and U-20-1959

Tanks U-28 through U-31 in Vista Tank System were constructed in 1963, and tanks U-33 through U-35 were completed in 1970.

The various structures had the following metal thicknesses:

- Pipelines 0.365 in.
- Tanks U-1 through U-31-0.313 in.
- Tanks U-33* through U-35-0.375 in.

Pipe-to-soil potentials were taken at various locations and are listed in Table 1. Soil samples were taken and forwarded to USA-CERL for analysis. Table 2 shows the results.

^{*}There is no tank U-32.

^{**}Causeway rectifier not activated; installed new August 1961.

^{***}Receiving some current from the GORCO (Guam Oil and Refining Company) cathodic protection system at this location because the two systems are electrically continuous.

[‡]Tenjo Vista rectifier on Marine Drive output: 0 amp at 11 V.

Using the soil data, material thicknesses, and years installed, PIPER made corrosion predictions. With no cathodic protection, the year of first leak for each structure should be:

- 1. Nimitz Hill rectifier (Sasa-to-NAS pipelines)—2003
- 2. CP test station 9 for Sasa-to-NAS pipelines, below Sanajania road -2013
 - 3. NAS pumphouse (Sasa-to-NAS pipelines)-2014
- 4. Pipelines at booster pumphouse off Marine Drive-1986
 - 5. Causeway/Sasa rectifier (pipelines)-2038
 - 6. U-35-1999
 - 7. U-28-1992
 - 8. U-5-1977
 - 9. U-20-1983

サイド できょうかん かんかん かいきん かいかい はいしゅう しゅうしゅう しゅうしゅう しゅうしゅ しゅうしゅう アンドラング アンドラング かんしゅう しゅうしゅう アンドラング しゅうしゅう しゅうしゅう しゅうしゅう しゅうしゅう しゅうしゅう しゅうしゅう しゅうしゅう しゅうしゅう

(Results are generalized for tanks surrounding the ones listed since soil data and tank thicknesses are the same.)

Figures 8 through 25 show year to first leak, CSI-versus-year-graphs, and cumulative leak tables. The reason for variations in these reports is that the soils at NSD Guam vary markedly, from a 710-ohm-m resistivity and 7.7 pH at U-35 to a 6750-ohm-m resistivity and 8.9 pH at the causeway rectifier.

Cathodic protection had been installed, but is in a state of disrepair at NSD Guam. Previous reports indicate this status has existed for many years. The PIPER analysis shows that better cathodic protection with state-of-the-art design must be installed at NSD Guam since the soils are so corrosive. The future version of PIPER that will include cathodic protection system monitoring may be implemented at NSD Guam when it is finished. Although it is impossible to determine the extent of the NSD Guam structures' corrosion (since cathodic protection has been

intermittent), leaks have been reported along the pipelines in the Sasa Valley Tank Farm.

It should be noted that the year-to-first-leak prediction would be affected by improved cathodic protection. Under optimal conditions, when cathodic protection is used, underground materials do not corrode.

4 ECONOMIC ANALYSIS

Factors affecting the repair/replace decision for corroded pipes include costs associated with the various alternatives, safety in residential and industrial areas, esthetic improvements, and ease of maintenance. Of these factors, economics are the most easily analyzed mathematically and, therefore, PIPER uses this parameter in evaluating repair and replacment alternatives.

PIPER has a set of economic analysis subroutines that simplifies and clarifies the budgetary process. The set consists of three programs: ECON, ECON1, and BUDOPT.

Factors in Repair/Replace Decisions

An economic analysis of repair and replacement must consider the following factors:⁵

- Total replacement cost
- Cathodic protection systems' cost
- Main-to-curb replacement cost in distribution systems
- Cost of gas lost while replacing pipe
- Cost incurred to restore service after replacement
- Pipe's salvage value
- Cost of reanoding at various intervals
- Cathodic protection monitoring cost
- Cost of gas lost due to leakage

^{*}NSD Guam Marianas Islands, Cathodic Protection Evaluation (Corrosion Engineering Research Co., Concord, CA, November 1979); R. T. Engleman, Cathodic Protection Survey, September 1971, U.S. Naval Activities, Guam, Marianas Islands (U.S. Navy Pacific Division, Naval Facilities Engineering Command, December 1971).

⁵ Procedure for Evaluating Pipeline Replacements (East Ohio Gas Company, 1979).

- Projected number of leaks needing repair in a given period
- Cost of examining pipeline condition (test holes)
- Cost associated with a typical repair.

Some of these costs occur only once, whereas others, such as cathodic protection monitoring, are cyclic. The three economic reports in PIPER can accommodate both types.

Several alternatives usually must be evaluated under the total replacement costs category. Should the replacement piping be coated and wrapped steel, or should it be polyethylene? If coated and wrapped steel is considered, which of the available coating systems should be used? Should the polyethylene piping be direct-buried or "sliplined" ("sliplining" refers to slipping a new plastic pipe through an old steel piping system)? Most often, the total cost associated with installing each alternative will be available in approximate dollar amounts (bids from previous contracts). A rough rule of thumb for direct-buried steel and plastic pipe is:

Direct-buried steel = diameter (in.) \times \$8/in. \times pipeline length

ANALYSIS TO CONTROL OF THE PROPERTY OF THE PRO

Direct-buried plastic = 69 percent of steel cost for 4 in. lines; 104 percent of steel cost for 6-in. lines.

Before choosing either steel or plastic piping, the costs peculiar to each material must be compared in addition to the material and installation costs. For example, in evaluating direct-buried plastic pipe, training and accidental damage expenses must be considered (workers inexperienced with plastic pipe will need training in installation and maintenance). In addition, fluid losses and repair costs associated with accidental damage must be estimated. Since the piping is installed just 3 ft underground, it is prone to accidental puncture from excavation or construction. In addition, renters at base housing may damage the piping through carelessness or vandalism.

Costs associated with cathodic protection implementation have been estimated at 3 to 5 percent of the cost for installing a new steel pipeline. Reanoding costs are critically contingent on successful care of the cathodic protection system. If care is taken to avoid electrical shorts and interference, typical replacement of the system will be 15 yr (actually, there will be a short remaining life at the end of the 15-yr period, but

replacement should be underway at that time to ensure protection from corrosion). Replacement costs should be the same 3 to 5 percent, adjusted for inflation. If electrical shorts or interferences are allowed to occur, anode life expectancy drops quickly (to as low as 5 yr or less). For this reason, adequate monitoring is essential.

Cathodic protection monitoring costs are difficult to obtain. Probably the most reliable way for an Army facility to ensure continued success of its installed cathodic protection systems is to award a contract for periodic inspection; contracting ensures accurate, timely cathodic protection surveys. A semiannual survey usually costs only a few thousand dollars. The contractors should be professional corrosion engineers who can assess the system status quickly and make recommendations for repair.

Example Analysis

To demonstrate how the reports in PIPER work, the following parameters are used in an example analysis:

- 6-in. line
- Initial cost of steel pipeline-\$2 million
- Cathodic protection installation costs—5 percent
- Cathodic protection monitoring costs: \$5000/yr, adjusted for inflation
- Salvage value of steel pipe-\$50,000
- Salvage value of plastic pipe-\$0
- Projected number of leaks for repair—will use PIPER's CSI prediction report, with resistivity equal to 5000 ohm-cm, pH 6, and the first year under consideration being year 20 of the pipeline's life
- Cost for each repair—\$3000 (includes detection, gas lost, light-up services, etc., adjusted for inflation in subsequent years).

The alternatives to be analyzed are:

- 1. Replace the existing pipeline with new steel pipeline
- 2. Replace the existing pipeline with new plastic pipeline

3. Continue to repair the existing pipeline.

(Numbers 1, 2, and 3 correspond to A, B, and C in the economic reports.)

The annual inflation rate is considered to be 6 percent and the interest rate is 0 percent (since military facilities use existing monies and do not pay interest).

Figure 26 is the first half of the CSI prediction report. As indicated, the expected year of first leak is 1982. Figure 27 is the graph table that accompanies the CSI prediction report in Figure 26 and shows that, by 1995, 82 cumulative leaks are predicted. Two leaks are projected for year 20 (1984).

Figure 28 shows the first economic analysis report, ECON. Here, the program has asked the user for (1) costs associated with each of several alternatives for each fiscal year of the analysis period and (2) the salvage value of each alternative at the end of the analysis period. The alternatives are analyzed for present worth based on user-specified inflation and interest rates. The user is left to determine the best present worth of the various alternatives.

The second report is ECON1, which is much more detailed and asks the user for initial and recurring costs. The user specifies differing cyclical costs, initial cost, inflation, and interest rates. (Figures 29 through 31 show which costs are yearly, which occur only once, and others, such as the cost of reanoding, that occur every 15 yr.) ECON1 can handle all of these situations. The output for each alternative is initial cost, present value, Equivalent Uniform Annual Cost (EUAC), and EUAC per area (EUAC/A). As Figures 29 through 31 show, the EUAC/A is greatest for continued repair, much less for replacement with steel pipe (five times), and least for replacement with plastic pipe.

Data from ECON1 are input into the subroutine BUDOPT, which selects the preferred alternative(s) for a given number of locations based on a benefit-to-cost ratio. The alternatives can be weighted with respect to importance and other variables. For example, a pipeline that serves a strategic function, such as refueling, might receive the highest priority, whereas a pipeline to an abandoned barracks would receive very low priority. Projects will be selected until a given budget is exceeded (Figure 32). Thus, BUDOPT is a tool with which to optimize facility monies.

For this example, the results of ECON, ECON1, and BUDOPT indicate replacement with plastic pipe is

the best available alternative if weighting factors are the same (identical benefit was used for each alternative).

5 FUTURE DEVELOPMENTS FOR PIPER

Most military facilities incorporate cathodic protection into their piping networks. However, the major problem in protecting underground structures is not designing and installing the necessary equipment, but rather maintaining it in working order. Potential problem sources are common: lawn mowers or earthmoving equipment damaging the system, plumbers eliminating dielectric unions, electricians grounding different systems onto the protected lines, birds building nests in rectifiers, rodents chewing holes in lines, and many others.

To help facilities with maintenance, USA-CERL is developing a Cathodic Protection Monitoring System as part of PIPER. This system will prompt the user for input (i.e., rectifier readings and test station readings) that she or he has gathered. It will then analyze the data, determine if problems exist, flag existing problems, and suggest "most probable cause" for the problem (e.g., "check for short circuit at Building A," or "anode ground bed resistance too high—check anode wires"). In addition, low-maintenance cathodic protection hardware will be developed.

Another proposed enhancement to PIPER will be graphic representation of piping ysstems, color-keyed to operating pressures. In addition, a microcomputer version of PIPER is being developed. When it becomes operational, "micro" PIPER will operate more economically than the CDC network version. The savings will stem from the difference in computer time costs between microcomputers and the commercial network. For noncomputational tasks such as inputting data, microcomputers are less expensive and no more time-consuming than minicomputers.

At present, PIPER evaluates gas piping systems exclusively. Future work will extend PIPER's applicability to water, sewage, and exhaust pipes as well as boilers and chillers. Using data and mathematical models compiled by private industry, CSIs pertaining to these pipes will be developed. Thus, a future version of PIPER will apply to all types of external and internal pipes.

6 conclusions

WY SERVICE BOYS LEED AND LEED OF THE CONTRACT OF THE CONTRACT

In continuing the search for nondestructive corrosion assessment techniques, USA-CERL has investigated a new electrical concept for checking underground pipelines. This "a.c. impedance" method is under development for use with the corrosion mitigation and management system PIPER.

The current computerized version of PIPER has been demonstrated at two military facilities Fort Riley, KS, and NSD Guam. Results indicate PIPER is successful in managing large amounts of data and in generating concise frequency and rank reports. The system helped identify failed piping at Fort Riley and correctly predicted leaks in NSD Guam's Sasa Valley pipelines (no cathodic protection assumed).
